

\* Differentiate and explain Contiguous file allocation system & linked list allocation

### Contiguous Allocation

- ⇒ Here, each file occupies a contiguous set of blocks on the disk.
- ⇒ It is contiguous
- ⇒ Directory entry contains -  
Address of starting Block
- ⇒ length of allocated portion
- ⇒ Both sequential and direct access are supported.
- ⇒ Not flexible in terms of file size

### Linked list allocation

- ⇒ Here, each file is a linked list of disk blocks, so,
- ⇒ It is not contiguous
- ⇒ Directory entry contains a pointer pointing to starting and ending file block
- ⇒ each Block contains pointer to next block
- ⇒ File Blocks are distributed randomly on disk.
- ⇒ flexible in terms of file size.

⇒ It is extremely fast

⇒ It is slow

⇒ It suffers from both internal and external fragmentation

⇒ It does not suffer from external fragmentation.

⇒ It support random or direct access

⇒ It does not support random access

⇒ Increasing file size is difficult

⇒ Increasing file size is easy

- (1) `lalloc` → It loops over the inode structures on the disk, one block at a time, looking for one that is marked free.
- (2) `namei` → It interprets its arguments as pathnames to any type of Unix file.
- Then, it follows each pathname until an endpoint is found.
- (3) `alloc` → It allocates memory within the current function stack frame.
- 2) memory allocated is automatically freed.
- (4) `ifree` → used for creating/deleting file.

⇒ Total head movement

$$\begin{aligned}
 &= (100 - 85) + (145 - 85) + (145 - 30) \\
 &= 15 + 60 + 115 \\
 &= 190 \\
 &=
 \end{aligned}$$

⇒ First request served ⇒ 100, then;

105, then 110 and then arm comes to service request for 90.

⇒ 80; disk would have serviced

3 request
